

# Object Composition

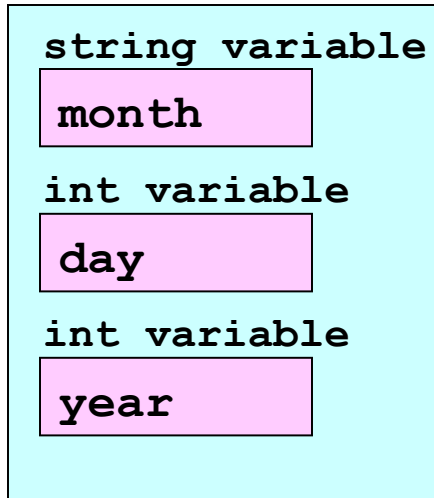

---

- This is when one object is a member variable of another class
- This relationship is called a *has-a* relationship

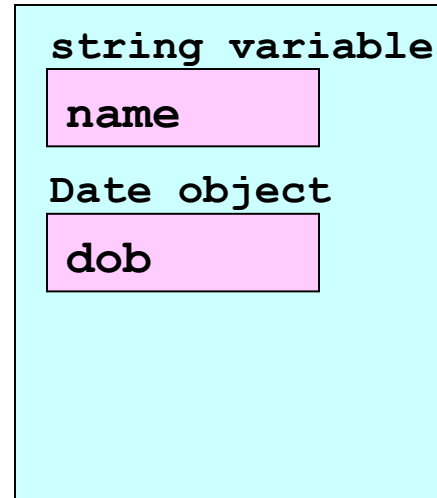

# Example

---

## Date Class

## Person Class

- Person class *has-a* Date object
- Let's look at the code that implements the above

# Date Class

---

```
class Date
{
private:
    string month;
    int day;
    int year;
public:
    Date(string month, int day, int year)
    { setDate(month, day, year); }
    Date() { setDate("January", 1, 1900); }
    void setDate(string month, int day, int year)
    { this->month = month; this->day = day; this->year = year; }
    string getMonth() { return month; }
    int getDay() { return day; }
    int getYear() { return year; }
};
```

# Person Class

---

```
class Person
{
private:
    string name;
    Date dob;    // has-a Date object (Composition)
public:
    Person(string name, string month, int day, int year)
    { this->name = name; dob.setDate(month, day, year); }
    void print()
    { cout << name << "'s birthday is on "
        << dob.getMonth() << " " << dob.getDay()
        << ", " << dob.getYear();
    }
};
```

# Main Function

---

```
Person buddy("Bill Stump",  
             "February", 5, 1975);  
  
buddy.print();
```

# Inheritance

---

- Classes that use inheritance are said to have an *is-a* relationship
  
- Examples:
  - Person *has-a* Date
  - Student *is-a* Person
  - Faculty *is-a* Person

# Protected Data Members and Functions

---

- Until now, we've been working with two access specifications:
  - private
  - public
- Another access specification is:
  - protected

# Protected

---

- Recall from the example last time, that Person class contained one private data member
  - `string name;`
- This meant that functions in the class Student (that is derived from Person) could not directly access Person's private data members
  - `Student(string aName) { name = aName; }`

# Protected

---

- Protected members of a class are just like private members, except that derived classes may access them directly

# Base Access Specifications

---

- Recall that Student was publicly derived from Person
  - `class Student : public Person`
- This is called the base access specification
- We could also use private or protected
  - `class Student : public Person`
  - `class Student : protected Person`
  - `class Student : private Person`

# Base Access Specifiers

---

Base class members

How base class members appear in derived class

```
private: x
protected: y
public: z
```

private  
base class

```
x inaccessible
private: y
private: z
```

```
private: x
protected: y
public: z
```

protected  
base class

```
x inaccessible
protected: y
protected: z
```

```
private: x
protected: y
public: z
```

public  
base class

```
x inaccessible
protected: y
public: z
```

# Constructors

---

- When creating an object of a derived class, which constructor is called first?
  - The base class first
  - Then the derived class
- When destroying an object of a derived class, which destructor is called first
  - The derived class first
  - Then the base class
