Spring 2014

Chapter 9 - Pointers

Reading: pp. 491-500

- Pointers are one of the most powerful features of C++
- Pointers give programmers more control over the computer's memory
- A pointer is the memory address of a variable
- A pointer is one of the most difficult and important concepts in C/C++

Pointer Declarations

- The memory address of a variable can be stored in another variable called a pointer
- Pointers are declared using the `*` operator
- The following declares a pointer to an integer
 - `int *pLength;`
- In the following statement, `length` is an integer and `pLength` is a pointer to an integer
 - `int *pLength, length;`

Pointer Problem

```
#include <iostream>

using namespace std;

int main ()
{
    char *pCh, ch;
    cout << "Size of pCh is " << sizeof (pCh) << endl;
    cout << "Size of ch is " << sizeof (ch) << endl;

    return EXIT_SUCCESS;
}
```

What is the difference between `pCh` and `ch`?

What is the output from the above program?

Address Operator

- How do we assign the address of a variable to a pointer?
- Use the address operator (**&**)
- **&** returns the operand's memory address
- Example:
 - **pLength = &length;**

Address Operator

- Address operator cannot be applied to constants
 - `int *pX, x = 5;`
 - `const int NUM = 98;`
 - `pX = &x` // NO ERROR
 - `pX = &NUM;` // ERROR
 - `pX = &8;` // ERROR

Pointer Operations

```
int x, *pX;
x = 8;    // set x to a value of 8
pX = &x;  // set the pointer variable to point
          // to the address of x

cout << "x is: " << x << endl;
cout << "Size of x is: " << sizeof(x) << endl;
cout << "Address of x is: " << pX << endl;
cout << "Address of x is: " << &x << endl;
```

Indirection Operator

- How can we use the pointer variable to modify the value in the variable?
 - i.e. how to use `pX` to change the value of `x`
- *Answer:* use the indirection operator (`*`)
- The `*` operator dereferences the pointer
 - You are actually working with whatever the pointer is pointing to
- Using the example on the previous slide
 - `cout << "Value pX is pointing to is: " << *pX << endl;`

Indirection Operator

- Change the value of **x** from 8 to 10 using the pointer variable?
- Change the value of **x** to a value entered by the user using the indirection operator?

Question

Exactly what happens when the following program is compiled and executed?

```
#include <iostream>

using namespace std;

int main ()
{
    int x, *pX;
    x = 8;
    *pX = 2;
    cout << "x = " << x << " *pX = " << *pX << endl;

    return EXIT_SUCCESS;
}
```

this Pointer

- functions - only one copy of each function exists in memory independent of the number of objects instantiated using the class declaration
- data members - each unique object of a particular class has space allocated for the data members of the class
- `this` - is a special built-in pointer available to a class's member functions. `this` points to the instance of the class making the function call
- `this` is passed as a hidden argument to all nonstatic member functions

RationalSet

- What do we return?

```
RationalSet RationalSet::add (const Rational &cRational)
{
    if (!isInSet (cRational))
    {
        mcRationals[mNumRationals] = cRational;
        ++mNumRationals;
    }
    return
}
```

Rational Interface

```
#ifndef RATIONAL_H
#define RATIONAL_H

using namespace std;

class Rational
{
public:
    Rational (int = 0, int = 1);
    void print (ostream &cOutput);

private:
    int mNumerator;
    int mDenominator;
};

#endif
```

Rational Implementation

```
#include "Rational.h"
```

```
Rational::Rational (int numerator, int denominator)
{
    (*this).mNumerator = numerator;
    (*this).mDenominator = denominator;
}
```

```
void Rational::print(ostream &cOutput)
{
    cOutput << mNumerator << '/' << mDenominator;
}
```

Accessing data members

Accessing data members using pointers

- `(*this).mNumerator` can be replaced with `this->mNumerator`
