Logical Operators and if/else statement

If Statement

- We may want to execute some code if an expression is **true**, and execute *some other code* when the expression is **false**.

- This can be done with two if statements…

```cpp
if( value >= LIMIT )
{
    // do something
}
if( value < LIMIT )
{
    // do something else
}
```

If/Else (4.3)

- C++ provides a shortcut to combine two **if** statements:

- The statements in the else clause are executed only when the expression is false.

```cpp
if( expression )
{
    // do stuff
}
else
{
    // do other stuff
}
```

Q.2 Example

```
int number;
cout << "Enter a number, I'll tell you";
cout << " if it is odd: ";
cin >> number;

// use an if/else statement here
```

If/Else: Syntax and Formatting

```
        if(expression)
        {
            // do stuff
        }
        else
        {
            // do other stuff
        }
```

- Note the braces with the `else` keyword and the alignment of the `else` under the `if` on its own line

If/Else: Braces

```
        if(expression)
        {
            // do stuff
        }
        else
            x += 9;
```
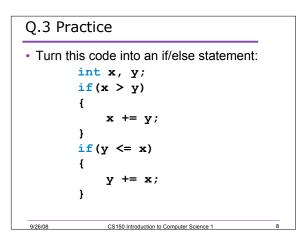

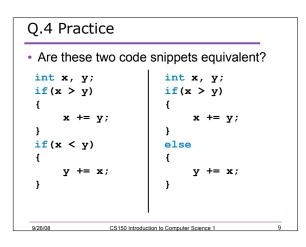

- Always use braces with the `else`!

If/Else: Commenting

```
// the expression I'm using here
// checks for . . .
if(expression)
{
    // if the expression is true
    // I need to ...
}
else
{
    // if the expression is false
    // I need to ...
}
```

Q.3 Practice

- Turn this code into an if/else statement:

```
int x, y;
if(x > y)
{
    x += y;
}
if(y <= x)
{
    y += x;
}
```

Q.4 Practice

- Are these two code snippets equivalent?

```
int x, y;                int x, y;
if(x > y)                if(x > y)
{                        {
    x += y;                  x += y;
}                        }
if(x < y)                else
{                        {
    y += x;                  y += x;
}                        }
```

if/else/if statements (4.4)

- What if there are more than two alternatives?

```cpp
if(expression1)
{
  statement1;
}
else if(expression2)
{
  statement2;
}
else
{
  default statement;
}
```

Q.5 Problem

- Write a C++ program segment that allows the user the ability to input an integer from the keyboard. If the integer is positive, increment a variable **poscount** by 1. If the integer is **negative**, increment a variable **negcount** by 1. If neither, increment **zerocount** by 1

Q.6 Problem

- Write a program that displays a letter grade corresponding to an exam score

  90 - 100 A

  80 - 89 B

  70 - 79 C

  60 - 69 D

  0 - 59 F

Nested if Statements (4.6)

- The second if is only executed if the first if conditional is **false**

- Note the indentation of the inner if

- There may be code between the { with the first else and the second **if**

```
if(x > y)
{
}
else
{
  if (x == 9)
  {
  }
  else
  {
  }
}
```

Q.7 Example

- Write nested if statements that perform the following test:

  o If amount1 is greater than 10 and amount2 is less than 100, display the greater of the two

- Can you write the solution to the above problem without nested if statements?

Using nested ifs

- Write a snippet of code that will do all of the following, where x and y are integers:

  o add y to x if x == y

  o add x to y if y > x

  o add 1 to x if (2 * y) == x

Logical Operators (4.7)

- If we want to check for more than one condition then we need to use logical operators

- These combine logical expressions (i.e. expressions that have a true/false value)

- There are three logical operators
  - &&   and
  - || or
  - !   Not

Q.8 Examples of Logical Operators

- `if((x > 7) && (x < 20))`

- `if((temp > 90.0) && (humidity > 0.9))`

- `if((salary < minSalary) || (dependents > 5))`

Evaluating Expressions: And &&

- `(expr1) && (expr2)`
- For the complete expression to be true, both expr1 and expr2 have to be true
- Example:
  - `(temp > 90.0) && (humidity > 0.9)`
  - These are unbearable heat and humidity conditions
  - Both must be true for the entire expression to be true

Evaluating Expressions: Or ||

- (**expr1 || expr2**)

- The complete expression is true if either expr1 or expr2 is true

- Examples:
  - o **(salary < minSalary) || (dependents > 5)**
  - o To qualify for financial aid, salary has to be less than some minimum salary or the number of dependents is greater than 5
  - o Only one condition has to be true

Evaluating Expressions: Not !

- **!expr**

- Unary operator

- Examples:
  - o **!((salary < minSalary) && (dependents > 5))**
  - o What makes this true? False?

Q.9 Example

- Your local bookstore has asked you to write a program to help them determine the cost of shipping of customers orders. If the order is $30 or less then shipping will cost $5, if the order is over $30 then shipping will be $3

Q.10 Problem

- The bookstore has now changed it's shipping policy so that
  o If the order is $30 or less, shipping is $5
  o If the order is over $30 but less than $50, shipping is $3
  o If the order is over $50 then shipping is $2

Operator Precedence

- We have now added relational, equality and logical operators to the mathematical operators that were introduced last week

- Where do the new operators fit in the precedence table?

Precedence

Precedence Operators   (Highest to Lowest)

`- (unary negation), ! (Logical NOT)`
`* / %`
`- +`

`<= => > <` `== !=`
`&&` `||`
`= += -= *= /= %=`

Q.11 Expression Evaluation

- According to the operator precedence and associativity rules given on the previous slide, how will the following expressions be evaluated?

  - `x < min + max`

  - `min <= x && x <= max`

  - `!x == y + 2`

  - `x = a + b % 7 * 2`

`exit()`

- To terminate a program we can use the `exit(int status)` function

  - This is a *function*, not part of the language
    - `#include<stdlib.h>`

  - The `status` is returned to the operating system to denote program success or failure
    - Success: 0
    - Failure: non-zero

Q.12 Practice

- Write a complete program that will ask the user for two integers. Display both integers to the screen if they are each greater than 1000 and terminate the program with `exit()` otherwise. Use exactly one `if/else`

Floating Point and Relational Operators

- Floating point math may not work out as you expect because of round off errors.
- In Math
  - 6 * 2/3 = 4
- In C++, where 0.66666 is equivalent to 2/3
  - 6.0 * 0.66666 =
  - 6.0 * 0.66667 =
  - 6.0 * 0.666666 =
  - 6.0 * (2.0 / 3.0) =

Q.1 Example

```
double result;

result = 6.0 * 0.666666;

if(result == 4.0)
{
   cout << "result == 4.0" << endl;
}

cout << setprecision(6) << fixed;
cout << result << endl;
cout << setprecision(2) << result;
cout << endl;
```

Example

```
#include "stdafx.h"
#include <iostream>
#include <iomanip>
using namespace std;

int _tmain(int argc, _TCHAR* argv[])
{

    double result;
    result = 6.0 * 0.666666;
    if( result == 4.0 )
    {
        cout <<" TRUE, result does equal 4.0" <<endl;
    }
    cout <<setprecision(6) <<fixed<< result <<endl;
    cout <<setprecision(2) <<fixed<< result <<endl;
    return std::
}
```

```
C:\WINDOWS\system32\cmd.exe
3.999996
4.00
Press any key to continue . . . _
```
