this Pointer, Constant Functions, Static Data Members, and Static Member Functions

this Pointer (11.1)

- functions - only one copy of each function exists in memory independent of the number of objects instantiated using the class declaration
- data members - each unique object of a particular class has space allocated for the data members of the class
- this - is a pointer that can be used to access an objects data members. No space associated with the class is allocated for the pointer this

Example of `this` pointer

```
#ifndef RATIONAL_H
#define RATIONAL_H

using namespace std;

class Rational
{
public:
  Rational(int, int);
  print();

private:
  int numerator;
  int denominator;
};

#endif
```

Example

```
#include "Rational.h"

Rational::Rational(int numerator, int denominator)
{
  (*this).numerator = numerator;
  (*this).denominator = denominator;
}

Rational::print()
{
  cout << numerator << '/' << denominator;
}
```

Pointers

- Accessing data members and pointers using pointers
- **`(*this).numerator`** can be replaced with
- **`this->numerator`**

Write the definition for setTime

```
class Time
{
  private:
    int hour;
    int minute;
    int second;
  public:
    Time();
    Time(int hour = 0, int minute = 0, int second = 0);
    int getHour();
    int getMinute();
    int getSecond();
    void setTime(int hour, int minute, int second);
    void printUniversal();
    void printStandard();
}; // end class Time
```

const

- Many things can be specified as const in C++
- Examples:
  - Objects
  - Member Functions
  - Data members
  - Function arguments

const Objects

- Principle of least privilege
- What happens when we declare any object to be a const?
- Example:
  - const int SIZE = 50;
- What do you think it means if I have
  - const Time dinnerTime(18, 30, 0);
- What member functions of class Time do you think dinnerTime can call?

const Member Functions

- A const object can only call const functions
- How do we declare member functions to be const?
  - Use the const keyword in both the function prototype and the function definition
  - Appears after the parameter list
- const member functions CANNOT modify data members (i.e. the current instantiation of the class)

Time Example

```
class Time
{
  private:
    int hour;
    int minute;
    int second;
  public:
    Time();
    Time(int = 0, int = 0, int = 0);
    int getHour() const;
    int getMinute() const;
    int getSecond() const;
    void setTime(int, int, int);
    void printUniversal() const;
    void printStandard() const;
}; // end class Time
```

Object Details

- What does memory look like after creating multiple objects of a class?
- For example:
  - `Time t(3, 45, 00);`
  - `Time t2(5, 29);`
  - `Time t3(14);`
  - `Time t4;`
  - `Time *pTime = new Time();`

`static` Class Members

- Each object gets it's own copy of the data members
- What if we wanted a data member to be shared between all objects
  - Each object sees the same value for the data member
  - Each object can modify that data member, and the other objects will see the change
- Data members of this type are called static

`static` Class Member (11.2)

- `static` members represent class-wide information and are not specific to one object
- There is only one copy of the member and it is shared between all objects
- Why would we ever need or want a static class member? Can you think of an example.

`static` Class Members

- They are not global variables
- The static data member could be declared public, private, or protected
- static data members must be initialized once

Example

```
#ifndef EMPLOYEE_H
#define EMPLOYEE_H
class Employee
{
  private:
    char *firstName;
    char *lastName;
    static int count;
  public:
    Employee(const char *,const char *);
    ~Employee();
    char *getFirstName() const;
    char *getLastName() const;
    static int getCount();
};
#endif
```

Constructor Definition

```
Employee::Employee(const char *, const char *)
{
  firstName = new char[strlen(first) + 1];
  strcpy(firstName, first);
  lastName = new char[strlen(last) + 1];
  strcpy(lastName, last);
  count++
}
```

What is the value of count?

```
int Employee::count = 0;

int main()

{

   Employee emp1("john", "doe");

   Employee emp2("jane", "doe");

   Employee emp3("bob", "doe");

}
```

static Member Functions

```
class IntVal
{
  private:
    int value;
    static int valCount;
  public:
    static int getValCount()
     { return valCount; }
};
```

Calling Static Functions

- Can be called independently of class objects, through the class name:

```
cout << IntVal::getValCount();
```

- Can be called before any objects of the class have been created
- Used mostly to manipulate static member variables of the class
