STACKADT

Stack

- The stack is a LIFO (Last-in First-out) linear data structure.
- The only data element that can be removed is the most recently added element.

Stack ADT Specification

- Elements: Stack elements can be of any type, but we will assume StackElement.
- **Structure**: Any mechanism for determining the elements order of arrival into the stack.

- **Domain**: The number of stack elements is bounded. A stack is considered full if the upper-bound is reached. A stack with no elements is considered empty.
- Operations: There are seven operations as follows:

function create (s: Stack, isCreated: boolean)

results: if s cannot be created, isCreated is false;
otherwise, isCreated is true, the stack is created and is
empty

function terminate (s: Stack)

results: stack s no longer exists

function isFull (s: Stack)

results: returns true if the stack is full; otherwise false is

returned

function is Empty (s: Stack)

results: returns true if the stack is empty; otherwise, false

is returned

function push (s: Stack, e: StackElement)

requires: isFull (s) is false

results: element e is added to the stack as the most

recent element

function pop (s: Stack, e: StackElement)

requires: isEmpty(s) is false

results: The most recently added element is removed and

assigned to e

function peek (s: Stack, e: StackElement)

requires: isEmpty(s) is false

results: The most recently added element is assigned to

e but not removed

Testing your Data Structure

- Your customer will abuse your data structure
- Your data structure should never crash the customer's code
 - code defensively
- Test each each function
 - test each functions requires statement
 - test boundary conditions (full/empty)
 - test bad input
 - test functions called in the wrong order

What are Stacks Useful for?

- Web browser history.
- "undo" in applications.
- Memory stack.

Ex. 1: Converting Decimal to Binary

- Here is an algorithm for converting a decimal number to its binary equivalent:
 - Read a number
 - While number is greater than 0
 - Find out the remainder after dividing the number by 2
 - Print the remainder
 - Divide the number by 2
 - End the iteration
- What is the problem with this algorithm?
- How can a stack be used to fix the problem?

Ex. 2: Balancing Parentheses

- Parentheses in algebraic expressions need to be balanced in order for the expression to be correct.
- Which of the following are valid expressions?

```
{a^2 - [ (c - d)^2 + (e - f)^2 ] }
{a - [ (b + c) ) ) - (d + e) ] }
{a - [ [ [ (b + c) - (d + e) ] }
{a - [ (b + c) - (d + e) } ]
```

 How can a stack be used to test if an expression's parentheses are balanced?

Stack Representation

In stk.h

```
#define MAX_STACK 1024

#define TRUE 1
#define FALSE 0

typedef short int BOOLEAN;
typedef char DATATYPE

typedef struct Stack
{
  int top;
  DATATYPE data[MAX_STACK];
} Stack;
```

Stack Functions

```
BOOLEAN stkCreate (Stack *);

BOOLEAN stkTerminate (Stack *);

BOOLEAN stkIsFull (Stack *);

BOOLEAN stkIsEmpty (Stack *);

BOOLEAN stkPush (Stack *, DATATYPE);

BOOLEAN stkPop (Stack *, DATATYPE *);

BOOLEAN stkPeek (Stack *, DATATYPE *);
```

Balancing Parentheses

 Assume that all of the functions have been implemented, how are you going to use a stack to test if parentheses are balanced?
