## Dynamic Programming

### Chapter 15

---

3/13/11 CS380 Algorithm Design and Analysis 1

---

---

---

---

---

---

---

---

## Dynamic Programming

---

- We know that we can use the divide-and-conquer technique to obtain efficient algorithms
- Sometimes, the direct use of divide-and-conquer produces really bad and inefficient algorithms

---

3/13/11 CS380 Algorithm Design and Analysis 2

---

---

---

---

---

---

---

---

## Fibonacci Numbers

---

- Fibonacci numbers are defined by the following recurrence:

$$F_n = \begin{cases} F_{n-1} + F_{n-2} & \text{if } n \geq 2 \\ 1 & \text{if } n = 1 \\ 0 & \text{if } n = 0 \end{cases}$$

<b>n</b>	0	1	2	3	4	5	6	7	8	9	10	...
<b>F<sub>n</sub></b>	1	1	2	3	5	8	13	21	34	55	89	...

---

3/13/11 CS380 Algorithm Design and Analysis 3

---

---

---

---

---

---

---

---

### A Recursive Algorithm

---

```
Algorithm Fibonacci(n)
if n <= 1, then:
  return 1
else:
  return Fibonacci(n-1) + Fibonacci(n-2)
```

- What is the running time?

---

---

---

---

---

---

---

---

### Finonacci

---

- Why is it so slow?
  
  
  
  
  
  
  
  
  
  
- Can we do better?
- Recursion is not always best!

---

---

---

---

---

---

---

---

### Dynamic Programming

---

- Not really dynamic
- Not really programming
- Name is used for historical reasons
- It comes from the term "mathematical programming", which is a synonym for optimization.

---

---

---

---

---

---

---

---

### Dynamic Programming

- Dynamic programming improves inefficient recursive algorithms
- How?
  - Solves each subsubproblem once and saves the answer in a table
- Used to solve optimization problems
  - Many possible solutions
  - Wish to find a solution with the optimal value

3/13/11 CS380 Algorithm Design and Analysis 7

---

---

---

---

---

---

---

---

### Four Steps for Dynamic Programming

- Characterize the structure of an optimal solution
- Recursively define the value of an optimal solution
- Compute the value of an optimal solution, typically in a bottom-up fashion
- Construct an optimal solution from computed information

3/13/11 CS380 Algorithm Design and Analysis 8

---

---

---

---

---

---

---

---

### Rod Cutting

- A company buys long steel rods and cuts them into shorter rods, which it then sells
- Each cut is free
- The management wants to know the best way to cut up the rods to make the most money

length $i$	1	2	3	4	5	6	7	8
price $p_i$	1	5	8	9	10	17	17	20

3/13/11 CS380 Algorithm Design and Analysis 9

---

---

---

---

---

---

---

---

### Example

- Can cut up a rod in  $2^{n-1}$  different ways
  - You can choose to cut or not cut after the first  $n-1$  inches
- What are the possible ways of cutting a rod of length 4 ( $n = 4$ )?
- What is the best way?

3/13/11 CS380 Algorithm Design and Analysis 10

---

---

---

---

---

---

---

---

### Initial Optimal Revenues

- Optimal revenues  $r_i$ , by inspection:

$i$	$r_i$	optimal solution
1	1	1 (no cuts)
2	5	2 (no cuts)
3	8	3 (no cuts)
4	10	2 + 2
5	13	2 + 3
6	17	6 (no cuts)
7	18	1 + 6 or 2 + 2 + 3
8	22	2 + 6

3/13/11 CS380 Algorithm Design and Analysis 11

---

---

---

---

---

---

---

---

### Optimal Revenues

- We can determine the optimal revenue  $r_n$  by taking the maximum of:
  - $p_n$ : price by not cutting
  - $r_1 + r_{n-1}$ : maximum revenue for a rod of length 1 and a rod of length  $n-1$
  - $r_2 + r_{n-2}$ : maximum revenue for a rod of length 2 and a rod of length  $n-2$
  - ...
  - $r_{n-1} + r_1$
- $m = \max(p_n, r_1 + r_{n-1}, r_2 + r_{n-2}, \dots, r_{n-1} + r_1)$

3/13/11 CS380 Algorithm Design and Analysis 12

---

---

---

---

---

---

---

---

### Optimal Substructure

- To solve a problem of size  $n$ , solve problem of smaller sizes. After making a cut, we have two subproblems. The optimal solution to the original problem incorporates optimal solutions to the subproblems.
- Example

3/13/11

CS380 Algorithm Design and Analysis

13

---

---

---

---

---

---

---

---

### Simplifying

- Every optimal solution has a leftmost cut. In other words, there's some cut that gives a first piece of length  $i$  cut off the left end, and a remaining piece of length  $n - i$  on the right
  - Need to divide only the remainder, not the first piece.
  - Leaves only one subproblem to solve, rather than two subproblems.
  - Say that the solution with no cuts has first piece size  $i = n$  with revenue  $p_n$ , and remainder size 0 with revenue  $r_0 = 0$ .

$$r_n = \max_{1 \leq i \leq n} (p_i + r_{n-i})$$

3/13/11

CS380 Algorithm Design and Analysis

14

---

---

---

---

---

---

---

---

### Recursive Top-Down Solution

```

CUT-ROD( $p, n$ )
if  $n == 0$ 
    return 0
 $q = -\infty$ 
for  $i = 1$  to  $n$ 
     $q = \max(q, p[i] + \text{CUT-ROD}(p, n - i))$ 
return  $q$ 
    
```

- Is it correct?
- Is it efficient?

3/13/11

CS380 Algorithm Design and Analysis

15

---

---

---

---

---

---

---

---

### Dynamic-Programming Solution

- Don't solve same subproblems repeatedly
- "Store, don't recompute"
  - Trade-off
- Can turn an exponential-time solution to a polynomial-time solution
- Two approaches:
  - Top-down with memoization
  - Bottom up

---

---

---

---

---

---

---

---

### Top-Down with Memoization

- Solve recursively, but store each result in a table
- To find the solution to a subproblem, first look in the table.
  - If there, use it
  - Otherwise, compute it and store in table

---

---

---

---

---

---

---

---

### Memoized Cut-Rod

```

MEMOIZED-CUT-ROD(p, n)
let r[0..n] be a new array
for i = 0 to n
    r[i] = -∞
return MEMOIZED-CUT-ROD-AUX(p, n, r)

MEMOIZED-CUT-ROD-AUX(p, n, r)
if r[n] ≥ 0
    return r[n]
if n == 0
    q = 0
else q = -∞
    for i = 1 to n
        q = max(q, p[i] + MEMOIZED-CUT-ROD-AUX(p, n - i, r))
r[n] = q
return q
    
```

---

---

---

---

---

---

---

---

### Bottom-Up

- Sort the subproblems by size and solve the smaller ones first

```

BOTTOM-UP-CUT-ROD( $p, n$ )
let  $r[0..n]$  be a new array
 $r[0] = 0$ 
for  $j = 1$  to  $n$ 
   $q = -\infty$ 
  for  $i = 1$  to  $j$ 
     $q = \max(q, p[i] + r[j - i])$ 
   $r[j] = q$ 
return  $r[n]$ 

```

---

---

---

---

---

---

---

---

### Running Time

- What is the running time of the previous two algorithms?

---

---

---

---

---

---

---

---

### Subproblem graphs

- Directed Graph:
  - One vertex for each distinct subproblem
  - Has a directed edge  $(x, y)$  if computing an optimal solution to subproblem  $x$  directly requires knowing an optimal solution to subproblem  $y$

---

---

---

---

---

---

---

---

### Subproblem Graph for Rod-Cutting

- When  $n = 4$ :

---

---

---

---

---

---

---

---

### Reconstructing a Solution

- We have only computed the value of an optimal solution
  - i.e. When  $n = 4$ ,  $r_n = 10$
- We still don't know how to cut up the rod!

---

---

---

---

---

---

---

---

### Rod-Cutting

EXTENDED-BOTTOM-UP-CUT-ROD( $p, n$ )

let  $r[0..n]$  and  $s[0..n]$  be new arrays

$r[0] = 0$

for  $j = 1$  to  $n$

$q = -\infty$

    for  $i = 1$  to  $j$

        if  $q < p[i] + r[j - i]$

$q = p[i] + r[j - i]$

$s[j] = i$

$r[j] = q$

return  $r$  and  $s$

Saves the first cut made in an optimal solution for a problem of size  $i$  in  $s[i]$ .

To print out the cuts made in an optimal solution:

PRINT-CUT-ROD-SOLUTION( $p, n$ )

$(r, s) = \text{EXTENDED-BOTTOM-UP-CUT-ROD}(p, n)$

while  $n > 0$

    print  $s[n]$

$n = n - s[n]$

---

---

---

---

---

---

---

---

### Example

- PRINT-CUT-ROD-SOLUTION(p, 8)

<i>i</i>	0	1	2	3	4	5	6	7	8
<i>r</i> [ <i>i</i> ]	0	1	5	8	10	13	17	18	22
<i>s</i> [ <i>i</i> ]	0	1	2	3	2	2	6	1	2

---

---

---

---

---

---

---

---

### Problem

- Do exercise 15.1-5 on page 370

---

---

---

---

---

---

---

---

### Summary

- Divide and Conquer is best used when there are no overlapping subproblems
- Otherwise, use dynamic programming!

---

---

---

---

---

---

---

---
