Trees

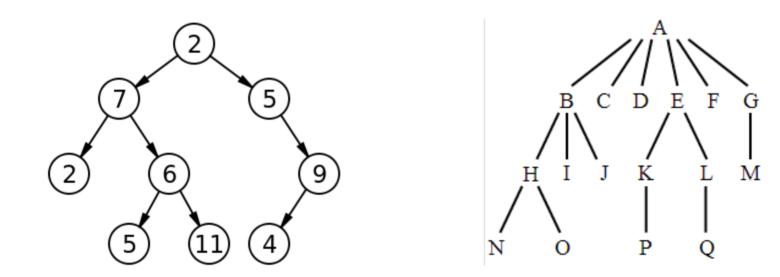

Until now, we have dealt with linear data structures such as:

- arrays
- linked lists
- stacks
- queues

A tree is:

- a nonlinear data structure where members may have multiple successors
- a data structure made up of nodes.

Trees

Tree Terminology

- root unique starting node
- parent predecessor of a node
- child successor of a node
- leaf a node with no children
- siblings two nodes with the same parent
- ancestors let A be an arbitrary node of a tree. If A is the root node, then A has no ancestors; otherwise, the parent of A and all ancestors of A's parent are ancestors of A

• What kind of definition is ancestor?

Tree Terminology

- descendants let B be an arbitrary node of a tree. If B is a leaf node, then B has no descendants; otherwise, each child of B and all descendants of each child of B are descendants of B.
- subtree an arbitrary node in the tree and all descendants of that node
- level the root node is level 1 and every other node in the tree is at level n where n is the number of nodes in the path from the root node to the node in question
- depth (or height) maximum level of any node in the tree

Identify Tree Attributes

For the given tree, identify:

a) root

b) parent of E

c) children of A

d) leaf nodes

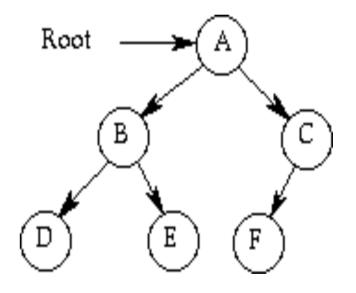

e) any two siblings

f) ancestors of B

g) descendants of F

h) level of D

I) depth of the tree

Binary Tree

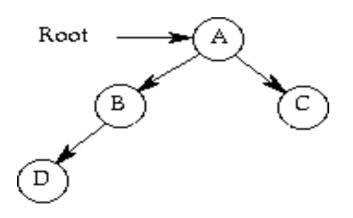

- Characteristics of a binary tree:
 - Each parent can have at most two children
 - A binary tree can be empty
 - If a binary tree has two children, the child on the left is the "left child " and the one on the right is the "right child"
- Note: The left child is the root of the left subtree and the right child is the root of the right subtree

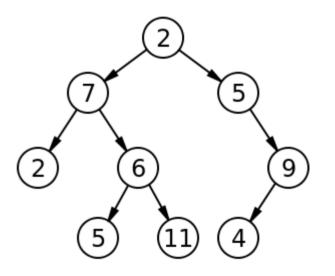

Some Binary Tree Operations

- Before defining the Binary Tree ADT, let's work a few problems.
- Write the appropriate data structure definitions for a binary tree.
- We can define three traversal methods for a binary tree:
 - inorder: Left, Visit, Right
 - preorder: Visit, Left, Right
 - postorder: Left, Right, Visit

Identify

• For the following binary tree, identify the inorder, preorder, and postorder traversals.

Binary Search Tree (BST)

- Consider an arbitrary node in a tree called A.
- All values in the left subtree are less than the value in A.
- All values in the right subtree are greater than the value in A.

Create BST

- Create a BST for the following strings (note: apr < jan):
- jan, feb, mar, apr, may, jun, jul, aug, sep, oct, nov, dec

Traversals

• If visiting a node means printing the contents of the node, show each of the following traversals of the newly created BST.

- preorder
- inorder
- postorder

BST Functions

- Write an algorithm for bstInsert.
- What is the worst case computing complexity of your algorithm? Why?
- Write the C function bstInsert.

BST Functions

- Write a C function bstFindLevel that returns the level of a node in a BST.
- Write a C function btFindLevel that returns the level of a node in a binary tree.
