

# Web Application Server CakePHP

Oct 31, 2011

[www.cakephp.org](http://www.cakephp.org)  
<http://book.cakephp.org/>

# More Complicated Database Usage Scenario

# Application Server

- The Application server helps put your code into the Model-View-Controller Design Pattern
  - Model: the data
  - View: display the data
  - Controller: connect them
- Helps to build some SQL commands
  - further separates you from the database
- M: Write code to produce a single row of data (many ways)
- V: Write code to display a single row of data (many ways)
- C: Mix and match!

# CakePHP

- Application Server for small to medium size web sites
  - Easy to install and configure!
  - Great on-line tutorial
  - Free!
- 
- I was able to get up and running in two afternoons

# Example

- We have data in a MySQL database

```
mysql> select * from employees;
+----+-----+-----+
| id | FName      | LName      | ....
+----+-----+-----+
| 1  | Emerald    | Wilkerson  | ....
```

- We want to display the data in different ways
  - filter differently
- Naming conventions!
  - in order to cut down on config files, CakePHP relies on standard naming conventions.
  - <http://book.cakephp.org/view/901/CakePHP-Conventions>

# Model app/models/employee.php

```
class Employee extends AppModel
{
    // var $name = 'employees';      // unnecessary if
                                    // the naming conventions are used.
    var $useDbConfig = 'al';        // from database.php

    function findFirst()
    {
        return $this->find('first');
    }

    function findLowestSalary()
    {
        return $this->find('first',
            array('order'=>array('salary ASC')));
    }

    function findHighestSalary()
    {
        return $this->find('first',
            array('order'=>array('salary DESC')));
    }
}
```

**Three ways to produce one row from table employee**

# Model employee.php

```
function findManagers()
{
    // select employees.*
    // from employees, software
    // where employees.id = Manager
    // order by id ASC;

    $options['joins'] = array
    (
        array
        (
            'table' => 'software',
            /* 'alias' => 'newName', */
            /* specify alias to rename the table software*/
            /* 'type' => 'LEFT', */
            /* don't specify type so use a plain join */
            'conditions' => array(
                'Employee.id = software.Manager',
            )
        )
    );
    $options['order'] = array('id ASC');
    return $this->find('all', $options);
}
```

```
SELECT *
FROM `employees` AS `Employee`
JOIN `software`
ON (`Employee`.`id` =
`software`.`Manager`)
WHERE 1 = 1
ORDER BY `id` ASC
```

# View app/views/employees/index\_single.ctp

```
<tr>
  <td>                                         Display one row of data
    <?php echo $theData['Employee']['id']; ?>
  </td>
  <td>
    <?php echo $theData['Employee']['FName']?>
  </td>
  <td>
    <?php echo $theData['Employee']['LName']?>
  </td>
  <td>
    <?php echo $theData['Employee']['Phone']?>
  </td>
  <td>
    <?php echo $theData['Employee']['Email']?>
  </td>
  <td>
    <?php echo $theData['Employee']['Salary']?>
  </td>
</tr>
```

# view index.ctp

```
<?php foreach ($theData as $employee) : ?>
<tr>
    <td><?php echo $employee['Employee']['id'] ; ?></td>
    <td><?php echo $employee['Employee']['FName'] ?></td>
    <td><?php echo $employee['Employee']['LName'] ?></td>
    <td><?php echo $employee['Employee']['Phone'] ?></td>
    <td><?php echo $employee['Employee']['Email'] ?></td>
    <td><?php echo $employee['Employee']['Salary'] ?></td>
</tr>
<?php endforeach; ?>
```

# Controller app/controllers/employees\_controller.php

```
class EmployeesController extends AppController {  
  
    // var $name = 'employees'; // not necessary  
  
    function index() { // default  
        // employees is the name of the variable to be set in the  
        // view that is used to display the result of find('all');  
  
        $this->set('theData', $this->Employee->find('all'));  
        // implicitly invoke index.ctp  
    }  
  
    function lowestSalary() {  
        $this->set('theData', $this->Employee->findLowestSalary());  
        $this->render('index_single');  
    }  
  
    function highestSalary() {  
        $this->set('theData', $this->Employee->findHighestSalary());  
        $this->render('index_single');  
    }  
}
```

# Controller employees\_controller.php

```
function salaryChartAll()
{
    $this->set('filter', 'All');

    $this->set('theData', $this->Employee->find('all'));
    $this->render('salary_chart');
}

function salaryChartManagers()
{
    $this->set('filter', 'Manager');

    $this->set('theData', $this->Employee->findManagers());
    $this->render('salary_chart');
}

function view($id) {
    $this->Employee->id = $id;
    $this->set('theData', $this->Employee->read());
    // implicitly invokes view.ctp
}
```

`https://gray/chadd/A1/Employees/salaryChartAll`

# Nuts & Bolts

- Configure database access
  - app/config/database.php
- cake/libs/view/layouts/default.ctp
  - wraps around your view
- app/webroot
  - space for .html files

```
class DATABASE_CONFIG {  
  
    var $default = array(  
        'driver' => 'mysql',  
        'persistent' => false,  
        'host' => 'localhost',  
        'login' => 'chadd',  
        'password' => 'xxxxx',  
        'database' => 'chadd_a1',  
        'prefix' => "",  
    );  
  
    var $a1 = array(  
        'driver' => 'mysql',  
        'persistent' => false,  
        'host' => 'localhost',  
        'login' => 'chadd',  
        'password' => 'xxxxx',  
        'database' => 'chadd_a1',  
        'prefix' => "",  
    );  
}
```

# Exercise

- I've put cake in /space/https/PUNetID/cake
  - done the configuration that needs root access
  - make cake/tmp writeable by the webserver
    - user wwwrun
- New database: PUNetID\_cake\_a1

```
mysql> use PUNetID_cake_a1;
mysql> source /tmp/cake_a1.sql;
mysql> show tables;
```
- Edit /space/https/PUNetID/cake/app/config/database.php
- Edit cake/app/config/core.php
  - Security.salt
  - Security.cipherSeed

<https://gray/PUNetID/cake>

# Exercise

- Add a Model
  - `cake/app/models/software.php`
    - produce all software
    - produce first, alphabetically
    - produce last, alphabetically
- Add a View
  - `cake/app/views/software/index.ctp` (display many rows)
  - `cake/app/views/software/single.ctp` (display one row)
- Add a controller
  - `cake/app/controllers/softwares_controller.php`
