## Bottom Up Parsing

Ch 4 p 195-215 + handouts!

Read chap 4 by Monday.

March 1, 2013

# The Plan

I hate wordy slides.  
This topic is too precise  
for me to get correct  
without lots of hints.

- Bottom Up Parsing
- Handles
- Shift/Reduce
- Operator Precedence Parsing
- Building Operator Precedence Tables
- Wednesday: Build an OPT in class

# Bottom Up Parsing

- Build parse tree from leaves and work up!
  - *Reduce* a string,  $w$ , to the start symbol,  $S$
- Reduction: replace a substring that matches the RHS of a production with the LHS of that production
  - *Right most derivation* is run in reverse.  
abbcde

<b>S</b>	->	<b>aABe</b>
<b>A</b>	->	<b>Abc   b</b>
<b>B</b>	->	<b>d</b>

# Algorithm

1) Look for a substring in  $w$  that matches the right side of any production.

2) Repeat step 1) with the new string  $w'$  until the start symbol  $S$  is produced (accept) or we run out of matching possibilities (reject)

abbcde

– Problems?

<b>S</b>	<b>-&gt;</b>	<b>aABe</b>
<b>A</b>	<b>-&gt;</b>	<b>Abc   b</b>
<b>B</b>	<b>-&gt;</b>	<b>d</b>

# Handle

<b>S</b>	->	<b>aABe</b>
<b>A</b>	->	<b>Abc   b</b>
<b>B</b>	->	<b>d</b>

- A ***handle*** is a substring of a string that matches some production's right side such that a reduction to a nonterminal on the left can be done in one step along the ***reverse of a rightmost derivation***.

abbcde

# Practice

- page 196/198

$E$	$\rightarrow$	$E + E$
$E$	$\rightarrow$	$E * E$
$E$	$\rightarrow$	$( E )$
$E$	$\rightarrow$	$id$

## Right Most Derivation

- Remember, we are doing bottom up parsing, so we start right here

$E$	$\Rightarrow$	$E + E$		
	$\Rightarrow$	$E + E$	$*$	$E$
	$\Rightarrow$	$E + E$	$*$	$id_3$
	$\Rightarrow$	$E + id_2$	$*$	$id_3$
	$\Rightarrow$	$id_1 + id_2$	$*$	$id_3$

- Ambiguous grammar so  $1+ \Rightarrow_{rm}$
- Handle Pruning

# How to choose a Handle

- Add a restriction

We'll see an *implementable* algorithm for this later.

- Defn[Aho]: "A handle of a right-sentential form  $\gamma$  is a production  $A \rightarrow \beta$  and a position of  $\gamma$  where the string  $\beta$  may be found and replaced by  $A$  to produce the *previous right-sentential form in the rightmost derivation* of  $\gamma$ .

That is, if  $S \Rightarrow_{\text{rm}}^* \alpha A w \Rightarrow_{\text{rm}} \alpha \beta w$ ,

then  $A \rightarrow \beta$  in the position following  $\alpha$  is a **handle** of  $\alpha \beta w$ ."

# Shift Reduce Parsing

- p199 ex4.24

```

E -> E + E
E -> E * E
E -> ( E )
E -> id
```

Stack	Input	Action
\$	id + id * id \$	shift
\$id	+ id * id \$	Reduce      E -> id
\$E	+ id * id \$	shift

# CONFLICTS!

- p 201

```
stmt -> if expr then stmt
      | if expr then stmt else stmt
      | other
```

- Some CFGs have unresolvable conflicts
  - shift/reduce
  - reduce/reduce

Stack	Input	Action
\$ ... if expr then stmt	else ... \$	?????

# Operator Precedence Parsing

- Form of Shift/Reduce parsing

This allows us to find handles!

- Two important properties for these shift-reduce parsers is that  $\epsilon$  does not appear on the right side of any production and no production has two adjacent nonterminals.

**E -> E + E**

**T -> + T T**

# Precedence

- We need to define three different precedence relations between pairs of terminals

Relation	Meaning
$a < . b$	<b>a yields precedence to b</b>
$a = . b$	<b>a has the same precedence as b</b>
$a > . b$	<b>a takes precedence over b</b>

They look like  $>$ ,  $<$ , and  $==$  but are very different

# Why?

- Identify each handle using the precedence rules and reduce the right-sentential string, based on the precedence relations, to a start (accept) state.

# Precedence Table

Define precedence relations between terminals.

$E$	$\rightarrow$	$E + T$	$ $	$T$
$T$	$\rightarrow$	$T * F$	$ $	$F$
$F$	$\rightarrow$	$id$		

		Input			
		$id$	$+$	$*$	$\$$
Stack	$id$		$> .$	$> .$	$> .$
	$+$	$< .$	$> .$	$< .$	$> .$
	$*$	$< .$	$> .$	$> .$	$> .$
	$\$$	$< .$	$< .$	$< .$	<b>accept</b>

# How does this work? (high level) p205

**\$ id + id \* id \$**

**\$ <. id >. + <. id >. \* <. id >. \$**

- Scan from left (to right) until the first **>.** is found
- Then, scan backwards (left) until a **<.** is found
- The handle is everything to the left of the **>.** and right of the **<.**
  - Including surrounding nonterminals

# In Code, p206 Algo 4.5

- How to find a handle
  - Use a stack
- 
- If the precedence relation  $<.$  or  $=.$  holds between the topmost terminal on the stack and the next input symbol, SHIFT
  - If the relation  $>.$  holds, REDUCE
  - No relation, SYNTAX ERROR

This is the solution to the bottom up assignment!

# Example

Handle/Output	Stack	Input	Reason
	\$	id + id * id \$	Start State
	\$ id	+id*id\$	\$ <. id

# Unary Operators

- In your grammar:  $*$ ,  $\&$ ,  $-$
- Example: Unary prefix operator
  - $\sim$  (not operator. Is not also a binary operator)
  - $X <. \sim$  for any op  $X$
  - $\sim >. X$  if  $\sim$  has higher precedence than  $X$ ,  
and  $\sim <. X$  otherwise

# Unary op is also a binary op

- \* is dereference and multiplication
- - is negation and subtraction
- & is not also binary
- Use lexer to return different token for
  - Dereference/Multiplication
  - Negation/Subtraction
- How?
  - Lexer needs to remember the previous token!
  - Cannot look ahead

# Define

- Operator-precedence grammar is an  $\epsilon$ -free operator grammar in which the precedence

relations  $\langle ., = ., \rangle$ . constructed as previous are disjoint. For any pair of terminals,  $a$  and  $b$ , never more than one of the relations  $a \langle . b$ ,  $a = . b$ ,  $a \rangle . b$  is true.

# Create Table

- Let  $G$  be an  $\varepsilon$ -free operator grammar
- For each two terminals  $a$  and  $b$  we say:
  - $a =. b$  if there exists a RHS:  $\alpha a \beta b \gamma$  where  $\beta$  is either  $\varepsilon$  or a single nonterminal.
  - $a <. b$  if for some NT  $A$ , a RHS  $\alpha a A \beta$  exists, and  $A \Rightarrow^+ \gamma b \delta$ , where  $\gamma$  is either  $\varepsilon$  or a single NT
  - $a >. b$  if for some NT  $A$ , a RHS  $\alpha A b \beta$  exists, and  $A \Rightarrow^+ \gamma a \delta$ , where  $\delta$  is either  $\varepsilon$  or a single NT

# LEADING, TRAILING

- **LEADING:** for each NT, those terminals that can be the first terminal in a string derived from that NT
- **TRAILING:** for each NT, those terminals that can be the last terminal in a string derived from that NT

# Leading/Trailing

$E$	$\rightarrow$	$E + T$	$ $	$T$
$T$	$\rightarrow$	$T * F$	$ $	$F$
$F$	$\rightarrow$	$(E)$	$ $	$id$

Nonterminal	First terminal	Last terminal
E		
T		
F		

# Compute Precedence

E	->	E + T		T
T	->	T * F		F
F	->	(E)		id

- For =. look for RHS with two terminals separated by nothing or a NT
- <. Look for RHS with a terminal immediately to the left of a NT (a, A in rule above) For each, a is <. to any terminal LEADING(A)
- >. Look for a RHS with a nonterminal immediately to the left of a terminal (A, b rule above). Every terminal TRAILING(A) >. b

# Compute Precedence
